Prevention of Nosocomial Infection through Application of Housekeeping

Qomariyatus Sholihah, Aprizal Satria Hanafi
Public Health Department, Faculty of Medicine, Universitas Lambung Mangkurat, Indonesia

ABSTRACT
The hospital has a high risk of nosocomial infection. Nosocomial infection can infect patients in hospital and can inhibit the patient's recovery, even worsen a patient. The purpose of this study was to determine the relationship of the application of housekeeping with the total number of germs floor as prevention nosocomial infection in the treatment room Roses in Ulin Hospital Banjarmasin, Indonesia. The study design was observational analytic. The study population was all Roses class treatment rooms. The samples were taken from the floor germs 4 point class treatment rooms in hospitals Rose Ulin. Sampling was conducted in the first week and the second week in November 2015. Paired t-test results showed no relationship between the application of housekeeping with the total number of germs floor with a p-value 0.015. This study found there was decreasing the total number of germ on the floor in all rooms. It is hoped that the hospital to continue to pay attention to the condition of the hospital, especially in terms of hygiene in order to avoid transmission of germs or nosocomial infections due to bacteria originating from the floor.

Keyword: Bacteria, Housekeeping, Nosocomial Infection

INTRODUCTION
Patient safety is part of the quality of hospital services. Many unsafe conditions are obtained when the patient is in the hospital. One of the unsafe conditions that can threaten the safety of patients is germs in hospitals [1]. The hospital is a health care institution for the community. Based on the understanding that the hospital can be considered as a gathering place for all kinds of diseases both infectious and non-infectious, so it can have negative impacts such as: 1) delays the healing process and recovery of the patient; 2) transmission of the disease to health care workers; 3) transmit the disease to the surrounding community; and 4) cause environmental pollution around the hospital [2].

Germ is an organism that was the most numerous and widespread compared to other organisms. Germ can act as pollutants, both outdoors and indoors. The spread of germs can happen anywhere, not least in the hospital environment. One of the spread of germs are hospital floor [3]. Cleanliness of floors greatly affect the incidence of nosocomial infections in hospitals [4]. Types of microorganisms are often potentially nosocomial infection are: Proteus sp., Escherichia coli, Staphylococcus aureus, Candida albicans, and Pseudomonas aeruginosa [5].

Nosocomial infection is a type of infection that occurs in hospital. This infection causes 1.4 million deaths every day worldwide. Additionally, the WHO in Elizabeth, et al also conducted a study that showed that about 8.7% of the 55 hospitals of 14 countries from Europe, Middle East, Southeast Asia and the Pacific showed a nosocomial infection and to Southeast Asia as much as 10.0% [6]. In Indonesia, nosocomial
infections reached 15.74%, far above the developed countries that only 4.8 to 15.5% [5]. Nosocomial infections can cause older patients treated at the Hospital. Data incidence of nosocomial infections in developing countries is not so clear. The numbers just came from several studies in several hospitals [7]. Nosocomial infection is a health care problem that often occurs. Nosocomial infections cause increased morbidity and mortality, additional days of treatment, and increase the cost of care [8].

Some incidence of nosocomial infection may not cause the patient’s death, but leads to longer patient treated in hospital [9], [10]. One effort to prevent nosocomial infections is by paying attention to sanitary aspects. Management of hospital sanitation is important to note, because the hospital is a health-care facilities for the general public. Environmental sanitation hospitals in controlling the growth of microorganisms can be accomplished through sterilization [11].

Sanitary installations hospitals, especially in the disinfection activities have a duty and responsibility to supervise and disinfection measures examination room, operating room, treatment room and an isolation room in an effort to prevent nosocomial infections [12]. Disinfection is an attempt to reduce the number of disease-causing microorganisms or potential pathogens such as bacteria, viruses, parasites and fungi [13], [14]. According to Krisetyowati, disinfection of hospital care room floor to do with Refisol. Mopping the floor using Refisol shown to decrease the number of bacteria in a hospital room floor [12].

Ulin Hospital Banjarmasin is the hospital doing medical activity. According to the annual report of the 10 diseases in Hospital Ulin Banjarmasin, especially in the Mawar room. The results of the examination conducted by Ulin Hospital said that the total number of germs on the floor of the treatment room in Ulin Hospital is 16 CFU / cm². This already exceeds the existing standards for total bacteria in the room which is about 5-10 CFU / cm². This is feared to cause nosocomial infections.

Contaminations of germs not only come from the patient or attendant. Pollution also comes from the environment such as air, floors, walls, water, foods and tools used [14]. Various actions may be taken to address the problem of pollution caused by the bacteria in the hospital, one of them by improving sanitation in hospitals. Implementation of sanitation is done by applying housekeeping. Based on the above researchers are interested to know the relationship of housekeeping application for prevention of nosocomial infection at the Mawar room treatment in the Ulin Hospital Banjarmasin.

2. RESEARCH METHOD

The study design was observational analytic. The object of this study is the number of bacteria on the floor throughout the Mawar treatment room at Hospital Ulin Banjarmasin. Sample is germs floor that take form 4 point in Rose treatment room at Ulin Hospitals Banjarmasin.

The study population was all class Roses treatment room. Samples are germs floor taken from the 4 point class Rose treatment room at Ulin Hospital Banjarmasin. Sampling was conducted in the first week and the second week of November 2015. The independent variable in this research is the application of housekeeping and the dependent variable is the total number of germs floor. Materials used in this study is the blood agar media, NaCl, ice cube and isolates germs from the floor of the Roses treatment room floor in Ulin Hospitals Banjarmasin are grown in media isolation.

The instrument used in this study is a sterile swab, petri plates, test tubes, Bunsen lamps, flasks, incubator, aluminum foil autoclave model no 1925 X. laminary flow and colony counter Stuart scientific. Sampling was conducted by using a cotton swab stick sterile floor at 4 points with a size of 1 cm² for every point. Sterile cotton stick dipped in 0.9% NaCl and then applied to the floor, the aluminum foil covering the plate was then opened, then apply a sterile cotton into Petri dishes containing blood agar media with zigzag manner. After it closed petri dish with aluminum foil, a petri dish containing the sample is then transported to the laboratory by using a flask containing ice.

Further planting and breeding blood agar medium that has been planted and then incubated at 37°C for 18-24 hours. Then measuring the colonies of bacteria that grow on blood agar media and numbered by using colony counter. Data are collected, processed and analyzed descriptively and presented in a frequency distribution table. The bivariate analysis performed using the statistical method which paired T test with significance level α = 0.05 to determine the relationship of the application of housekeeping with the total number of germs floor.

3. RESULTS AND ANALYSIS

3.1. Univariate Analysis

The focus of the research are total number of germs floor before and after implementation of housekeeping in the Roses treatment room Hospitas Ulin Banjarmasin. Table 1 shows the differences in the
number of germs in the 4 treatment rooms before and after the implementation of housekeeping. Data showed all the rooms has decreased the number of germs floor after implementation of housekeeping.

<table>
<thead>
<tr>
<th>Room</th>
<th>Result (Before)</th>
<th>Result (After)</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>11 CFU/cm²</td>
<td>1 CFU/cm²</td>
</tr>
<tr>
<td>5</td>
<td>12 CFU/cm²</td>
<td>1 CFU/cm²</td>
</tr>
<tr>
<td>6</td>
<td>10 CFU/cm²</td>
<td>2 CFU/cm²</td>
</tr>
<tr>
<td>9</td>
<td>16 CFU/cm²</td>
<td>4 CFU/cm²</td>
</tr>
</tbody>
</table>

Source: Primary Data

3.2. Bivariate Analysis

The results of the bivariate analysis done is paired T test to determine the relationship between the application of housekeeping (independent variable) with the total number of germs floor (the dependent variable) can be seen in Table 2.

<table>
<thead>
<tr>
<th>Variabel</th>
<th>Paired Differences</th>
<th>Std. Deviation</th>
<th>Std. Error Mean</th>
<th>Sig. (2-tailed)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Germs1</td>
<td>Germs2</td>
<td>11.311</td>
<td>2.806</td>
<td>.935</td>
</tr>
</tbody>
</table>

Paired T test results with a confidence level of 95% to get the value of \( p = 0.015 \). P value of statistical test results obtained in Ho decision rejected (\( p \) value <0.05), which means there is a relationship between the application of housekeeping with total number of germs floor. The problem of nosocomial infection is a major problem in every hospital [15]. This is even more troubling, because nosocomial infections can increase morbidity, mortality, financial loss and the duration of hospital care [16], [17]. The hospital environment is always in contact with humans, in this case the hospital personnel, patients and the various ways either direct or indirect contact with air or intermediary vectors [18]. Germs flooring risk causing nosocomial infection in patients [19].

According Quinn et al studies, the factors that influence the number of bacteria on the floor of the treatment room one of them is the frequency of cleaning the floor [20]. Decrease in number of bacteria caused by the application of housekeeping floor with a mop floor Rose room treatment on a daily basis. After treatment for a few days decreased number of bacteria floor based on the results of laboratory tests.

Based on the Ministry of Health Republic of Indonesia 1204 / Menkes / SK / X / 2004 about the Hospital Healthy Environment Standard maximum total number of germs in the floor of the treatment room is 5-10 CFU / cm² [21]. Figures floor germs that exceed the requirements of the hospital environment can trigger nosocomial infections. Appropriate measures necessary to prevent nosocomial infections in hospitals, one of which is to conduct regular disinfection.

In the hospital there are sick people who carry germs and are potential sources of infection for others. In an effort to tackle the incidence of nosocomial infections, a review of the epidemiology of the problem of contamination and nosocomial infection needs to be done because it is basically the incidence of nosocomial infections involving the human element, the environment and microbes, which are inter-related to each other [22].

The high number of bacteria floors can be caused by various factors such as the use of disinfectant dose is not appropriate, how to use a disinfectant that is not good and mopping the floor that is not done routinely [23], [24]. Additionally, the high number of bacteria floor was also influenced by other factors such as patients, visitors, animals and insects as well as the air. Giving disinfectant on the floor will kill microorganisms that can cause disease. Appropriate disinfectant dosing would reduce the number of germs in the hospital floor. These germs can live and thrive on the floor of the hospital [25], [26].

Disinfection is an effort to reduce / eliminate the amount of pathogenic microorganisms that cause disease (not including spores) [27]. Mopping with a disinfectant is an attempt to clean the floor with a way to chemically reduce and eliminate the pathogenic microorganisms that cause disease [28]. Application of housekeeping will create a work environment that is clean, hygienic, and safe. Besides useful for the implementation of hospital housekeeping can also help employees achieve personal discipline. Quality of the work must be guaranteed as early as possible in the workplace. Improve work efficiency and reduce operating costs [29].

Prevention of Nosocomial Infection through Application of Housekeeping (Qomariyatus Sholihah)
One of the principles that can be applied housekeeping is cleaning by killing germs on the floor of the treatment room to perform disinfection. Disinfection can be done to mop floors with a disinfectant containing NaOH and Banzalkonium Chloride has the ability to kill germs. OH ions of sodium hydroxide are ionized in the water as a disinfectant (germ killers). Given the hospital as a place that is prone to germs, spraying is required in a hospital environment to eliminate the total number of germs on the floor of the hospital [12], [30].

Additionally disinfection treatment room floor can be made using disinfectant phenol 1%. Ammonium kuatener is one disinfecting floors and an aldehyde-free active against bacteria, micro-bacteria, fungi, viruses (HBV, HIV, HCV, rota, adeno, papova, Noro). The floor area of the hospital is also on the wane and is not eligible health with the increasing number of visitors resulting in increased number of bacteria on the floor [31],[32]. Increased number of bacteria floor will trigger a nosocomial infection. Nosocomial infections will increase health care costs due to the increased length of stay in hospital, treatment with expensive drugs (such as antiretroviral drugs for HIV / AIDS, and antibiotics), and the use of other services (such as laboratory tests, rontsen, transfusion). Consequently, in countries with low resources, prevention of nosocomial infection should be considered much more important in the effort to improve health services in hospitals and other healthcare facilities will be made [33],[34].

Hospital environment unfavorable will allow the transmission of a disease that will affect public health in the hospital environment. Therefore, hospital sanitation services should be organized in order to create a clean environment so it can support the healing of patients and can prevent the transmission of nosocomial infections in the hospital environment.

4. CONCLUSION

Based on the results of laboratory tests the total number of germs on the floor of the 3 Rose’s treatment room, Hospital of Ulin Banjarmasin has met the environmental standards of health services after the implementation housekeeping. After application of housekeeping there is a decrease in the total number of germs on the floor. The results of the bivariate analysis using paired T test also showed that there are differences in the number of the total number of germs on the floor between before and after application of housekeeping.

ACKNOWLEDGEMENTS

Thanks to Allah SWT for the gift that has been given. Thanks to all stakeholders who support the passage of this research.
